A: It's the Intel Management Engine component driver. I believe this is only for servers. You are trying to install this on your home computer. The Intel Management Engine Component Driver for Windows 7 and Windows Server 2008 R2, version 2.1.0.0 may be installed by the following method: Log on as a member of the local Administrators group. Click Start, point to Programs, point to Intel® Device Manager, and then click Intel Management Engine Component Driver. Click the Update Driver button. If necessary, accept the License terms and conditions. Select the driver from the list of matching drivers, and then click Install. Click OK. If necessary, restart the computer.

A: I had this same problem on my Windows 7 laptop. There's an update to the Intel Management Engine Component Driver on their website. You can get this from: It's a 3rd-party.MSI installer that could be downloaded from the link in the article, and ran. If you have trouble opening and downloading it, I've posted the download link in the comments. Here are the instructions from the website: 1. Log on as a member of the local Administrators group. 2. Click Start, point to Programs, point to Intel® Device Manager, and then click Intel® Management Engine Component Driver. 3. Click the Update Driver button. 4. If necessary, accept the License terms and conditions. 5. Select the driver from the list of matching drivers, and then click Install. 6. Click OK. 7. If necessary, restart the computer. The important part is "Select the driver from the list of matching drivers". The other parts aren't needed. It is generally accepted that in high speed signaling systems, the output drivers operate at a higher voltage than the circuitry used for addressing the memory cells. This is because the speed of the signaling is generally faster than the speed of the memory read or write cycle. Additionally, writing to memory requires generally higher voltages than reading memory. These factors force memory circuitry to use a different part of
